ERA: A LLM-Ontology informed Goalbased Agent for Fake News Detection

Group 6 | Riccardo, Tijmen, Ruben, Luc, Lars, Vedant

Problem

Solution

With the emergence of internet people are more prone to fake news than ever. We want to detect and explain why the given piece of information is factually/logically invalid.

We propose a solution to identify fake news using a goal based agent which queries our trusted ontology and a LLM to arrive at the decision whether the given information is real or fake. Result

ERA is a goal-based agent designed to evaluate the truthfulness of news by reasoning through various arguments. It provides

- Verdict on the credibility of the information
- Supporting evidence both for and against the statement, potentially supplemented by relevant references.

Scenarios

- Running is good for your Health
- Consuming sugary food helps with Diabetes Mellitus

Agent Architecture

Ontology

- New concepts: Human, Environment
- USE: The HermiT reasoner is queried with the mapped nlp sentence
- Query formulation: retrieve instances belonging to Intersection (all instances for Universal existence), fallback to DBpedia
